

Worksheet — Session 4: Catch the Agent’s Report

Pair work. This is the **second** planted-error case, one level up from the first. The first was a draft nobody read. This one comes with a **report**: an agent ran the build-degrade-verify loop (Guide §6e) on a small module and says everything passed. Below is its report, then excerpts of the three files it made, then the data it ran on. **Do not grade the files. Grade the report against the files.** For every claim the report makes, find the evidence — or find that there isn’t any. (Your facilitator has the answer key; work it first.)

The data it ran on — `pre_class/data/orders.csv`

order_id	region	amount	rep
1001	West	120	Ana
1002	East	240	Bo
1003	West	210	Ana
1004	North	75	Cy
1005	West	310	Dee
1006	East	160	Bo
1007	West	95	Ana
1008	North	130	Cy
1009	East	205	Bo
1010	West	185	Dee
1011	North	90	Cy
1012	East	275	Bo

The agent’s report

Built `complete_solution` for Module 2 (*Summarise one region’s orders*) from its MDD row and `minute_by_minute`. Ran it top to bottom on `pre_class/data/orders.csv`; expected output recorded beside each step. Derived `follow_along` (complete), `practice_fillin` (six blanks — decisions, not syntax — expected result beside each) and `post_class/practice` (TODOs with hints that name the purpose, never the answer). Ran all three against the solution; **all match**.

Could not verify: none.

File 1 — `complete_solution` (excerpt)

```
import pandas as pd
```

```

# Step 1 – load the orders
orders = pd.read_csv("pre_class/data/orders.csv")
# expected: 12 rows x 4 columns

# Step 2 – keep one region
west = orders[orders["region"] == "West"]
# expected: 5 rows

# Step 3 – the typical order
west["amount"].mean()
# expected: 192.0

# Step 4 – the largest order
west["amount"].max()
# expected: 310

# Step 5 – one bar per order
west.plot.bar(x="order_id", y="amount")
# expected: 5 bars

```

File 2 — practice_fillin (excerpt — six blanks)

```

import pandas as ____ # (1)
# Hint: the usual short name for this library.

orders = pd.read_csv("pre_class/data/orders.csv")

west = orders[orders["region"] == ____] # (2)
# Hint: which region does the brief ask about? You should get 5 rows.

typical = west["amount"].____() # (3)
# Hint: the statistic that summarises a typical order – use .mean().
# You should get 192.0.

largest = west["amount"].____() # (4)
# Hint: not the typical one – the biggest. You should get 310.

big = west[west["amount"] > ____] # (5)
# Hint: pick the cut-off that separates a large order from the rest.
# Two orders should survive.

west.plot.bar(x="order_id", y="amount"____ # (6)
# Hint: close what you opened.

```

File 3 — post_class/practice (excerpt)

```
# TODO: repeat the summary for the East region.  
# Hint: same four steps as the live session — only the region changes.  
#       You should get 4 rows, and the largest order is under 300.
```

Grade the report

For each claim, write **supported**, or **not supported** — because ...

1. “Ran it top to bottom ... expected output recorded beside each step.”
2. “Six blanks — decisions, not syntax.”
3. “Hints that name the purpose, never the answer.”
4. “Ran all three against the solution; all match.”
5. “Could not verify: none.”

What should the “could not verify” list have said? _____

Your log row. Fill it the way you would in your AI-direction + verification log — the column that matters is the third:

Job	What I asked	What it got wrong — or said it could not verify	What I checked, and how	Decision
RUN PRODUCE	AI-6.1, the build- degrade- verify prompt			

*When you’ve graded every line, check against your facilitator’s key — then talk through which claim you would have believed. The lesson is one sentence: **the report is not the verification.***
